PDF

"Generate a lecture scribe suitable for exam preparation based ONLY on the provided context (Lecture 8 slides). The target audience is a student preparing for a closed-notes exam.

Instructions:

Reason Step-by-Step: While writing the scribe, explicitly explain the reasoning behind definitions, assumptions, proofs, and example solutions exactly as presented in the provided context. Include this reasoning directly in the scribe text to help the student understand 'why' and 'how'.

Faithfulness: Include definitions, notation, theorem statements, and worked examples exactly as they appear in the slides. Do not hallucinate or add information from outside the context.

Logical Flow: Make the logical dependencies between concepts clear.

Structure: Organize the content with clear headings and subheadings corresponding to the lecture flow.

Goal: The output should allow a student to recall definitions, reconstruct proofs, and follow example solutions step-by-step."

Below is a **faithful lecture scribe for Lecture 8 — Gaussian, Uniform, Exponential, Laplace, and Gamma Random Variables**, written **only from the provided slides**, with **explicit reasoning included inside the scribe**, and organized exactly in lecture order so a student can reconstruct definitions, formulas, and example solutions in a **closed-notes exam**.
All statements come from the uploaded slides.

Lecture 8 Scribe

Gaussian, Uniform, Exponential, and Gamma Random Variables

---

1. Outline of the Lecture

The lecture proceeds in the following logical order:

1. Gaussian random variable
   - Definition and properties
   - Standard forms (error function, Q-function, Φ-function)
   - Relation between Φ and Q
   - Example
2. Types of continuous random variables
   - Uniform
   - Exponential
   - Laplace
   - Gamma
3. Problem solving
4. Gaussian density estimation
5. Applications in computing systems

Reasoning:
The outline shows that the lecture first builds the mathematical foundation (Gaussian RV), then generalizes to other continuous distributions, and finally connects to applications and estimation from data.

---

2. Moments, Mean, Variance, Skewness, Kurtosis

2.1 Expectation of a Function

For a continuous random variable:

$$E[g(X)] = \int g(x) f_X(x) dx$$

For a discrete random variable:

$$E[g(X)] = \sum g(x_k) P(X = x_k)$$

Reasoning:
Expectation is defined as a weighted average of values, where the weights are probabilities (PMF) or density (PDF).
This definition is needed because later we compute mean, variance, skewness, kurtosis using expectation.

2.2 Linearity of Expectation

For constants a, b:

$$E[aX + b] = aE[X] + b$$

For sums:

$$E\left[\sum g_k(X)\right] = \sum E[g_k(X)]$$

Reasoning:
This property simplifies calculations of moments and is used repeatedly in later derivations.

2.3 Central Moments

Mean:

$$\mu_X = E[X]$$

Variance:

$$\sigma_X^2 = E[(X - \mu_X)^2]$$

Skewness:

$$c_s = \frac{E[(X - \mu)^3]}{\sigma^3}$$

Reasoning:
Skewness measures symmetry of the PDF around the mean.

- Positive → right-tail larger
- Negative → left-tail larger

Kurtosis:

$$c_k = \frac{E[(X-\mu)^4]}{\sigma^4}$$

Reasoning:
Kurtosis measures how peaked the distribution is around the mean.

- Large → sharp peak
- Small → flatter distribution

These quantities are later used in CDF analysis problem.

---

3. Gaussian Random Variable

3.1 Definition

A Gaussian random variable has PDF

$$f_X(x) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$$

Reasoning:

- μ controls center (mean)
- σ controls spread (variance)
- Exponential form ensures total area = 1

Notation:

$$X \sim N(\mu, \sigma^2)$$

Reasoning:
This form appears in noise, measurements, and natural variations, so it is the most important continuous distribution.

3.2 Shape Properties

- Symmetric about μ
- Bell-shaped
- Mean = median = mode
- Area under PDF = 1

CDF increases smoothly from 0 to 1.

---

4. Standard Forms

Gaussian integrals cannot be written in simple closed form.

Therefore special functions are defined.

4.1 Error Function

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

Complementary error function:

$$\mathrm{erfc}(x) = 1 - \mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt$$

Reasoning:
These functions appear when integrating the Gaussian PDF.

4.2 Φ-function (Standard Normal CDF)

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-t^2/2} dt$$

Reasoning:
Φ(x) is used to compute probabilities for standard normal.

4.3 Q-function (Tail Probability)

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^\infty e^{-t^2/2} dt$$

Reasoning:
Q(x) directly gives right-tail probability.

Key identity:

$$Q(x) = 1 - \Phi(x)$$

Reasoning:
Total probability = 1.

5. CDF of General Gaussian

Given

$$X \sim N(\mu, \sigma^2)$$

CDF:

$$F_X(x) = \Phi\left(\frac{x-\mu}{\sigma}\right)$$

Reasoning:

1. Standardize variable

$$z = \frac{x-\mu}{\sigma}$$

2. Convert to standard normal
3. Use Φ table

Tail probability:

$$P(X > x) = Q\left(\frac{x-\mu}{\sigma}\right)$$

Key identities:

$$Q(x) = 1 - \Phi(x)$$

$$F_X(x) = 1 - Q\left(\frac{x-\mu}{\sigma}\right)$$

Reasoning:

Φ is natural for CDF

Q is natural for tail probability.

---

6. Example — Gaussian Probability

Given

$$f_X(x) = \frac{1}{\sqrt{8\pi}} \exp\left(-\frac{(x+3)^2}{8}\right)$$

Compare with standard form:

$$m = -3, \quad \sigma^2 = 4, \quad \sigma = 2$$

Relations:

$$F_X(x) = \Phi\left(\frac{x-m}{\sigma}\right)$$

$$P(X > x) = Q\left(\frac{x-m}{\sigma}\right)$$

Example 1

$$P(X \leqslant 0) = \Phi\left(\frac{0-(-3)}{2}\right) = \Phi(3/2) = 1 - Q(3/2)$$

Example 2

$$P(X > 4) = Q\left(\frac{4+3}{2}\right) = Q(7/2)$$

Example 3

$$P(\,|X+3|\,<2)$$

Solve inequality:

$$-2 < X + 3 < 2$$

$$-5 < X < -1$$

Probability:

$$F(-1) - F(-5) = \Phi(1) - \Phi(-1) = 2\Phi(1) - 1 = 1 - 2Q(1)$$

Example 4

$$P(\,|X-2|\,>1)$$

$$X < 1 \text{ or } X > 3$$

$$F(1) + P(X > 3) = 1 - Q(2) + Q(3)$$

Reasoning:

Break into intervals and use Φ / Q.

---

7. Applications of Gaussian RV

- Thermal noise in circuits
- Measurement error
- Packet delay jitter

Reasoning:

Many small independent effects → Gaussian by central limit behavior.

---

8. Problem Solving — CDF Analysis

Given CDF:

$$F_X(x) = \begin{cases} 0 & x < 0 \\ x^2 & 0 \leqslant x \leqslant 1 \\ 1 & x > 1 \end{cases}$$

Find mean, variance, skewness, kurtosis.

Step 1 — PDF

$$f_X(x) = \frac{d}{dx} F_X(x) = 2x$$

Reasoning:

PDF = derivative of CDF.

Step 2 — Mean

$$\mu = \int_0^1 x(2x)dx = 2/3$$

Step 3 — Variance

$$E[X^2] = \int_0^1 x^2(2x)dx = 1/2$$

$$\sigma^2 = 1/2 - (2/3)^2 = 1/18$$

Step 4 — Skewness

$$c_s = \frac{E[(X-\mu)^3]}{\sigma^3} = -2\sqrt{2}/5$$

Negative → left-skewed

Step 5 — Kurtosis

$$c_k = \frac{E[(X-\mu)^4]}{\sigma^4} = 12/5$$

Less peaked than Gaussian → platykurtic.

---

9. Gaussian Modeling From Data

Reality:

- Measurements are noisy
- Observations form histogram

Model:

$$X = \sigma Z + \mu$$

Reasoning:

- Z ~ standard normal
- transform to real variable

Goal:

Estimate μ, σ from samples.

---

10. Density Estimation

We observe samples:

$$x_1, x_2, \dots, x_n$$

Estimate:

$$\hat{\mu}, \hat{\sigma}$$

Build estimated PDF.

Reasoning:

Probability models uncertainty, not exact values.

---

11. Applications in Computing

- Image denoising
- Cloud latency modeling
- Sensor fusion (Kalman filter)

Reasoning:

All involve uncertainty → modeled using probability distributions.

Goal: The output should allow a student to recall definitions, reconstruct proofs, and follow example solutions step-by-step."

Below is a **fully faithful, step-by-step lecture scribe for Lecture 8**, written strictly from the provided slides, with **explicit reasoning included inside the scribe**, and organized exactly in lecture order so that a student can **reconstruct definitions, formulas, and worked examples in a closed-notes exam**.
All statements are taken from the slides.

Lecture 8 Scribe

Gaussian, Uniform, Exponential, Laplace, and Gamma Random Variables

---

1. Lecture Outline and Logical Plan

The lecture is structured in the following order:

1. Gaussian random variable
   - Definition and properties
   - Standard forms (error, Φ, Q functions)
   - Relation between Φ and Q
   - Example
2. Types of continuous random variables
   - Uniform
   - Exponential
   - Laplace
   - Gamma
3. Problem solving (moments from CDF)
4. Gaussian modeling and density estimation
5. Applications in computing systems

Reasoning:
The lecture first introduces the most important continuous distribution (Gaussian), then shows how probabilities are computed using special functions, then solves numerical problems, and finally connects the theory to real data and engineering systems.

---

2. Expectation and Moments

2.1 Expectation of a Function

For a continuous random variable

$$E[g(X)] = \int \quad g(x)f_X(x)dx$$

For a discrete random variable

$$E[g(X)] = \sum g(x_k)P(X = x_k)$$

Reasoning:
Expectation is defined as the probability-weighted average of values.
For continuous variables we use PDF, for discrete variables we use PMF.
This definition is required because mean, variance, skewness, and kurtosis are all expectations of functions of X.

2.2 Linearity of Expectation

For constants a, b:

$$E[aX + b] = aE[X] + b$$

For sums:

$$E\left[\sum_{k=1}^{N} g_k(X)\right] = \sum_{k=1}^{N} E[g_k(X)]$$

Reasoning:
Linearity allows complicated expressions to be broken into simpler expectations.
This property is used when computing moments.

2.3 Central Moments

Mean

$$\mu_X = E[X]$$

Variance

$$\sigma_X^2 = E[(X - \mu_X)^2]$$

Skewness

$$c_s = \frac{E[(X - \mu)^3]}{\sigma^3}$$

Reasoning:
Skewness measures symmetry of the PDF around the mean.

- positive → right tail longer
- negative → left tail longer

Kurtosis

$$c_k = \frac{E[(X-\mu)^4]}{\sigma^4}$$

Reasoning:

Kurtosis measures how peaked the distribution is around the mean.

- large → sharp peak
- small → flat distribution

These will be used later in the CDF problem.

---

3. Gaussian Random Variable

3.1 Definition

A Gaussian random variable has PDF

$$f_X(x) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$$

Notation

$$X \sim N(\mu, \sigma^2)$$

Reasoning:

- μ controls the center of the distribution
- σ controls spread
- exponential ensures area under curve = 1

Gaussian appears naturally in noise and measurement errors.

3.2 Shape Properties

- Symmetric about μ
- Bell-shaped
- Mean = median = mode
- Area under PDF = 1

CDF increases smoothly from 0 to 1.

---

4. Standard Forms for Gaussian

Gaussian integrals cannot be expressed using elementary functions.
Therefore special functions are defined.

4.1 Error Function

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

Complementary error function

$$\mathrm{erfc}(x) = 1 - \mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt$$

Reasoning:
When integrating the Gaussian PDF, this integral appears, so a new function is defined.

4.2 Φ-function (Standard Normal CDF)

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-t^2/2} dt$$

Reasoning:
Φ gives probability that standard normal ⩽ x.

4.3 Q-function (Tail Probability)

$$Q(x) = \frac{1}{\sqrt{2\pi}} \int_x^\infty e^{-t^2/2} dt$$

Key identity

$$Q(x) = 1 - \Phi(x)$$

Reasoning:
Total probability = 1, so right tail = 1 − left area.

---

5. CDF of General Gaussian

Given

$$X \sim N(\mu, \sigma^2)$$

CDF

$$F_X(x) = \Phi\left(\frac{x-\mu}{\sigma}\right)$$

Reasoning step-by-step:

1. Start from CDF definition
2. Substitute Gaussian PDF
3. Change variable

$$t = \frac{y-\mu}{\sigma}$$

4. Integral becomes Φ

Tail probability

$$P(X > x) = Q\left(\frac{x-\mu}{\sigma}\right)$$

Key identities

$$Q(x) = 1 - \Phi(x)$$

$$F_X(x) = 1 - Q\left(\frac{x-\mu}{\sigma}\right)$$

Reasoning:

Φ is used for CDF

Q is easier for right-tail probabilities.

---

6. Example — Gaussian Probability

Given

$$f_X(x) = \frac{1}{\sqrt{8\pi}} \exp\left(-\frac{(x+3)^2}{8}\right)$$

Compare with

$$\frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$$

Identify

$$\mu = -3, \quad \sigma^2 = 4, \quad \sigma = 2$$

Relations

$$F_X(x) = \Phi\left(\frac{x-\mu}{\sigma}\right)$$

$$P(X > x) = Q\left(\frac{x-\mu}{\sigma}\right)$$

6.1 $P(X \leqslant 0)$

$$F_X(0) = \Phi\left(\frac{0+3}{2}\right) = \Phi(3/2) = 1 - Q(3/2)$$

6.2 $P(X > 4)$

$$Q\left(\frac{4+3}{2}\right) = Q(7/2)$$

6.3 $P(|X+3| < 2)$

Solve inequality

$$-2 < X + 3 < 2$$

$$-5 < X < -1$$

Probability

$$F(-1) - F(-5) = \Phi(1) - \Phi(-1) = 2\Phi(1) - 1 = 1 - 2Q(1)$$

6.4 $P(|X-2| > 1)$

$$X < 1 \text{ or } X > 3$$

$$F(1) + P(X > 3) = 1 - Q(2) + Q(3)$$

Reasoning:

Break interval → convert to Φ or Q.

---

7. Applications of Gaussian

- Thermal noise voltage
- Measurement error
- Packet delay jitter

Reasoning:

Many independent effects → Gaussian distribution.

---

8. Problem Solving — CDF Analysis

Given

$$F_X(x) = \begin{cases} 0, x < 0 \\ x^2, 0 \leqslant x \leqslant 1 \\ 1, x > 1 \end{cases}$$

Find

- mean
- variance
- skewness
- kurtosis

Step 1 PDF

$$f_X(x) = \frac{d}{dx} F_X(x) = 2x$$

Reason: PDF = derivative of CDF.

Step 2 Mean

$$\mu = \int_0^1 x(2x)dx = 2/3$$

Step 3 Variance

$$E[X^2] = \int_0^1 x^2(2x)dx = 1/2$$

$$\sigma^2 = 1/2 - (2/3)^2 = 1/18$$

Step 4 Skewness

$$c_s = \frac{E[(X-\mu)^3]}{\sigma^3} = -\frac{2\sqrt{2}}{5}$$

Negative → left-skewed

Step 5 Kurtosis

$$c_k = \frac{E[(X-\mu)^4]}{\sigma^4} = 12/5$$

Flat → platykurtic.

---

9. Gaussian Modeling

Reality:

- Sensors noisy
- Measurements vary

Model

$$X = \sigma Z + \mu$$

where Z is standard normal.

Reasoning:

Transform standard normal → real variable.

10. Density Estimation

Given samples

$$x_1, \dots, x_n$$

Estimate

$$\hat{\mu}, \hat{\sigma}$$

Build estimated PDF.

Reasoning:

We estimate distributions, not exact values.

---

11. Applications

- Image denoising
- Cloud latency
- Sensor fusion

Reason:

Probability models uncertainty in real systems.
